

**DATA** Drone<sup>5</sup><sup>TM</sup>  
for SYBASE

has been designed from the ground up for the purpose of simplifying data migrations from Informix databases and DB2 to SYBASE. It is really comprised to two different highly modular systems. The first is responsible for actually migrating the data from one system to the other. This is accomplished by first converting the schemas from system specific SQL to ANSI standard SQL, and then by converting it from ANSI standard into system specific SQL for the new database. It is important that we do it this way so that **DataDrone5** can be expanded in the future to support more databases than just Informix and DB2.

The second system is the source migration system. This system is responsible for converting source code so that it connects to the new database, functions properly with the new database, and cleanly disconnects from the new database. This challenge is accomplished by different modules for different types of source. These modules will use the same system specific SQL to ANSI SQL to new system specific SQL module that the data migration system uses.

..... (the migration application)
